More memory chips would require more space, and they have limited real world usage. Once the memory chips are all in use, you can't use any more because they are all already in use. Only the computer can put more memory chips into the drive without actually using all of them. If you want to know what's going on, try to run something like Memtest86 (it's free) and see if the memory chips are behaving normally or not. I have a pen drive that can't be used because I have only one memory chip, and I have a laptop that can't be used because I have only 2GB of memory. The thing is, the memory chips that are still in the drive behave like they have 4GB of memory. In fact, the space is like 4GB, and there is no "cache" (for example, the CPU never has to read the entire RAM before saving a small part of it to a cache to speed up the next time you need to access the RAM). When you try to write a file, the cache might be "full", and the writing fails. When you read a file, the cache might be "empty" or "almost full", and the reading fails. I didn't think that a 4GB chip could be better than a 32GB one, but if you think about it, it's true. See what happens in the "official" test with Memtest86.

Anandamide uptake and metabolism by human brain microvascular endothelial cells. In the brain, there are two different cannabinoid receptors (CB1 and CB2), both of which regulate brain inflammation and immunity. Endogenous cannabinoids also modulate blood-brain barrier (BBB) permeability, but the role of specific uptake and degradation systems is unknown. We show here that the human BBB microvascular endothelial cells (HBMECs) express both CB1 and CB2 and, at the same time, express a high affinity and a low capacity uptake system for anandamide (AEA), a main endocannabinoid in the brain. HBMECs express the key enzymes of AEA catabolism, namely, fatty acid amide hydrolase (FAAH) and monoacylglycerol lipase (MAGL), both of which are responsible for AEA degradation. Our data show that uptake and catabolism are pharmacologically relevant processes in the BBB. In particular, low AEA levels, produced in the brain 82157476af
